

Metal Industry Indicators

Indicators of Domestic Primary Metals, Steel, Aluminum, and Copper Activity

August 2009

The primary metals leading index increased for the fourth consecutive month in July, and posted its first positive 6-month smoothed growth rate in over a year. While growth rates are fast approaching the threshold that signals an increase in industry activity, a recovery in the primary metals industry is not necessarily imminent. It is uncertain when economic conditions in the United States will improve enough to support an upturn in domestic primary metals industry activity. The metals price leading index growth rate has risen well above the 1.0% threshold that indicates further increases in metals price growth, however a pullback in China's metals stockpiling could undermine sustained metals price growth in the near term.

The primary aluminum and the aluminum mill products indexes are suspended because of discontinued availability of industry-specific historical data. The USGS will continue to calculate the steel and copper composite indexes.

The **primary metals leading index** increased 3.7% in July to 130.2 from a revised 125.5 in June. The index's 6-month smoothed growth rate, a compound annual rate that measures the near-term trend increased to 0.8% from a revised -8.7% in June. A growth rate above +1.0% is usually a sign of an upward near-term trend for future metals activity, while a growth rate below -1.0% indicates a downward trend. For an explanation of these indexes and a definition of the primary metals industry, [see page 10](#).

Three of the four available index components increased in July, and one declined. The JOC-ECRI metals price leading index growth rate made the largest positive contribution, 1.5 percentage points, to the net increase in the leading index. It has steadily grown since the beginning of the year and moved into positive territory in July. The average workweek in primary metals establishments in July was one-half hour longer than in June, which was the shortest since just after the 1981-82 recession. It contributed 1.2 percentage points to the leading index. The Institute for Supply Management's PMI is on the brink of the threshold that denotes an increase in U.S. manufacturing activity. It added another 1.2 percentage points. In contrast, the stock price index combining construction and farm machinery companies and industrial machinery companies eased back, contributing -0.2 percentage points to the leading index. The primary metals leading index will likely be revised next month when the remaining four components become available.

The accelerating primary metals leading index over the last 4 months and its positive growth rate strongly suggest that the

decline in primary metals activity has ended. Economic conditions in the United States and other countries need to stabilize before increased metals demand can occur. Activity growth in the U.S. primary metals industry is most likely to be slow in the near future.

The **steel leading index** increased 1.1% in June, the latest month for which it is available, to 102.5 from a revised 101.4 in May, and its 6-month smoothed growth rate increased to -5.3% from a revised -9.8% in May. Movement among its components was mixed in June. New orders for iron and steel products and the S&P stock price index for steel companies made the major positive contributions to the leading index. The decreased inflation-adjusted M2 money supply growth rate offset much of the gains in other components. The steel leading index growth rate is still negative and is not yet indicating an end to the decline in U.S. steel industry activity in the near term.

The **copper leading index** increased 2.0% in June from a revised 107.9 in May, and its 6-month smoothed growth rate increased to -4.5% from a revised -10.1%. A rebound in overtime hours in copper rolling, drawing, extruding, and alloying plants accounted for more than half of the gain in the copper leading index. The index for new housing permits issued also rebounded in June, making another substantial positive contribution to the leading index. Decreases in new orders for nonferrous metals products and the S&P index for building products companies prevented the leading index from rising higher in June. The negative copper leading index growth rate is indicating that decreases may continue in near-term domestic copper activity.

Metals Price Growth Poised to Continue

The **metals price leading index** increased 1.7% to 110.3 in June, the latest month for which it is available, from a revised 108.5 in May. Its 6-month smoothed growth rate increased to 13.7% from a revised 10.6% in May. Two of its three available indicators increased. However, the first positive growth rate of the trade-weighted average exchange value of other major currencies against the U.S. dollar in nearly a year made the largest contribution, 1.5 percentage points, to the net increase in the leading index. A wider yield spread between the U.S. 10-year Treasury Note and the federal funds rate contributed 0.6 percentage points. In contrast, the declining growth rate of the inflation-adjusted value of new orders for U.S. nonferrous metal products pulled the leading index down 0.3 percentage points. The fourth component, the growth rate of the Economic Cycle Research Institute's (ECRI) 19-Country Long Leading Index, is only available through May. It has risen into positive territory, indicating an increase in economic activity for most major

industrialized countries. This index signals changes in the growth of economic activity about 5 months in advance. The metals price leading index signals major changes in the growth rate of nonferrous metals prices an average of 8 months in advance.

The growth rate of the inflation-adjusted value of U.S. non-ferrous metal products inventories, which is an indicator of supply and usually moves inversely with the price of metals, sank in June. The negative metal inventories growth rate and the high metals price leading index growth rate indicate continued metals price growth. However, metals oversupply in China, which is a major metals consumer, could undermine price growth.

The business cycle and inventories are only two factors in metal price determination. Other factors that affect prices include changes in metals production, speculation, strategic stockpiling, foreign exchange rates, geopolitical instability, and production costs.

NA: Not available r: Revised

Note: The components of the Leading Index of Metal Prices are the spread between the U.S. 10-year Treasury Note and the federal funds rate, and the 6-month smoothed growth rates of the deflated value of new orders for nonferrous metal products, the Economic Cycle Research Institute's 19-Country Long Leading Index, and the reciprocal of the trade-weighted average exchange value of the U.S. dollar against other major currencies. The Metal Industry Indicators (MII) Nonferrous Metals Price Index measures changes in end-of-the-month prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange (LME). The steel scrap price used is the price of No. 1 heavy melting. Inventories consist of the deflated value of finished goods, work in progress, and raw materials for U.S.-produced nonferrous metal products (NAICS 3313, 3314, & 335929). Six-month smoothed growth rates are based on the ratio of the current month's index or price to its average over the preceding 12 months, expressed at a compound annual rate.

CHART 6.
COPPER: LEADING AND COINCIDENT INDEXES, 1987-2009

CHART 7.
COPPER: LEADING AND COINCIDENT GROWTH RATES, 1987-2009

Explanation

Each month, the U.S. Geological Survey tracks the effects of the business cycle on five U.S. metal industries by calculating and publishing composite indexes of leading and coincident indicators. Wesley Mitchell and Arthur Burns originated the cyclical-indicators approach for the economy as a whole at the National Bureau of Economic Research in the mid-1930s. Over subsequent decades this approach was developed and refined, mostly at the National Bureau, under the leadership of Geoffrey H. Moore.¹

A business cycle can briefly be described as growth in the level of economic activity followed by a decline succeeded by further growth. These alternating periods of growth and decline do not occur at regular intervals. Composite indexes, however, can help determine when highs and lows in the cycle might occur. A composite index combines cyclical indicators of diverse economic activity into one index, giving decision makers and economists a single measure of how changes in the business cycle are affecting economic activity.

The indicators in the metal industry leading indexes historically give signals several months in advance of major changes in a coincident index, a measure of current metal industry activity. Indicators that make up the leading indexes are, for the most part, measures of anticipations or new commitments to various economic activities that can affect the metal industries in the months ahead.

Composite coincident indexes for the metal industries consist of indicators for production, shipments, and total employee hours worked. As such, the coincident indexes can be regarded as measures of the economic health of the metal industries.

The metal industry coincident indexes reflect industry activity classified by the U.S. Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS). Of the five metal industries, primary metals (NAICS 331) is the broadest, containing 25 different metal processing industries. Steel, aluminum, and copper are specific industries within the primary metals group.

The SIC was the main vehicle used by the U.S. Government and others in reporting industry economic statistics throughout most of the last century. Starting with the 1997 U.S. Economic Census, the U.S. Government began using the NAICS, which classifies economic data for industries in Canada, Mexico, and the United States. In general, metal industry indexes starting in 1997 begin to reflect the NAICS classification, while indexes for earlier years follow the SIC. Hence, composite indexes from 1997 forward are not entirely consistent with those of earlier years.

The largest change to primary metals because of the NAICS deals with other communication and energy wire manufacturing (NAICS 335929). Under NAICS, this manufacturing has been removed from primary metals and added to electrical equipment, appliance, and component manufacturing. Because monthly shipments and new orders for this wire are not available, the USGS is estimating their values from 1997 onward and adding them to the appropriate metal industry indicators and indexes to maintain consistency.

¹Business Cycle Indicators, A monthly report from The Conference Board (March 1996).

There are other small changes to the primary metals industry because of the switch to the NAICS. Coke oven activity not done by steel mills, for example, is removed and alumina refining, a part of industrial inorganic chemical manufacturing under the SIC, is added. Since the historic trends of the composite indexes are not affected by these small changes, the USGS is not making specific adjustments to the indexes for them for the periods before and after 1997.

The metal industry leading indexes turn before their respective coincident indexes an average of 8 months for primary metals and 7 months for steel and copper. The average lead time for the primary aluminum leading index is 6 to 8 months, and the average lead time for the aluminum mill products leading index is 6 months.

The leading index of metal prices, also published in the *Metal Industry Indicators*, is designed to signal changes in a composite index of prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange. On average, this leading index indicates significant changes in price growth about 8 months in advance.

The growth rate used in the *Metal Industry Indicators* is a 6-month smoothed growth rate at a compound annual rate, calculated from a moving average. Moving averages smooth fluctuations in data over time so that trends can be observed. The 6-month smoothed growth rate is based upon the ratio of the latest monthly value to the preceding 12-month moving average.

$$\left[\left(\frac{\text{current value}}{\text{preceding 12-month moving average}} \right)^{\frac{12}{6.5}} - 1.0 \right] * 100$$

Because the interval between midpoints of the current month and the preceding 12 months is 6.5 months, the ratio is raised to the 12/6.5 power to derive a compound annual rate.

The growth rates measure the near-term industry trends. They, along with other information about the metal industries and the world economy, are the main tools used to determine the outlook of the industries. A 6-month smoothed growth rate above +1.0% usually means increasing growth; a rate below -1.0% usually means declining growth.

The next update for these indexes is scheduled for release on the World Wide Web at 10:00 a.m. EDT, Friday, September 18. The address for *Metal Industry Indicators* on the World Wide Web is: <http://minerals.usgs.gov/minerals/pubs/mii/>

The *Metal Industry Indicators* is produced at the U.S. Geological Survey by the Minerals Information Team. The report is prepared by Gail James (703-648-4915; e-mail: gjames@usgs.gov) and Ken Beckman (703-648-4916; e-mail: kbeckman@usgs.gov). The former Center for International Business Cycle Research, under the direction of Dr. Geoffrey H. Moore, and the former U.S. Bureau of Mines developed the metal industry leading and coincident indexes in the early 1990s. Customers can send mail concerning the *Metal Industry Indicators* to the following address:
